

Quantifying the star formation history  
of the Milky Way disk in the Solar neighborhood

Edouard Bernard  
Observatoire de la Côte d'Azur

# Context: the formation of disk galaxies

- Disk galaxies made of thin and thick disks, bulge, halo
- Each composed of different stellar populations
  - when did these structures form?
  - how do they relate to each other?
  - what mass fraction formed *in-situ*?

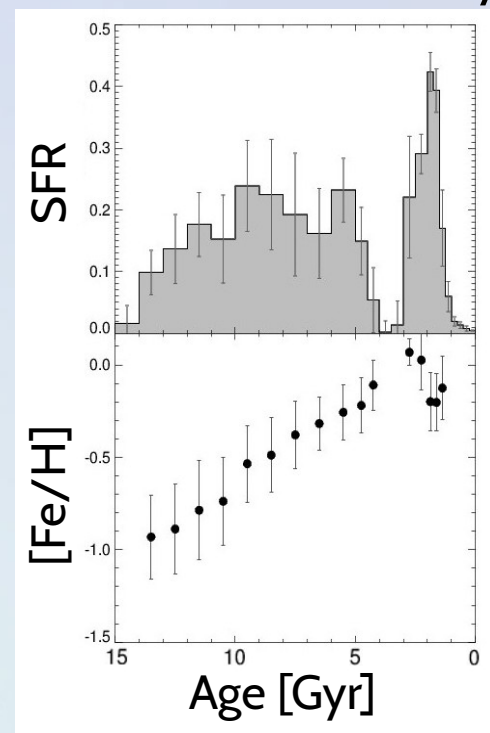

Credit: Swinburn University of Technology

# Context: the formation of disk galaxies

- Disk galaxies made of thin and thick disks, bulge, halo
- Each composed of different stellar populations
  - when did these structures form?
  - how do they relate to each other?
  - what mass fraction formed *in-situ*?

Reconstruct their star formation history (SFH)

## Star formation history

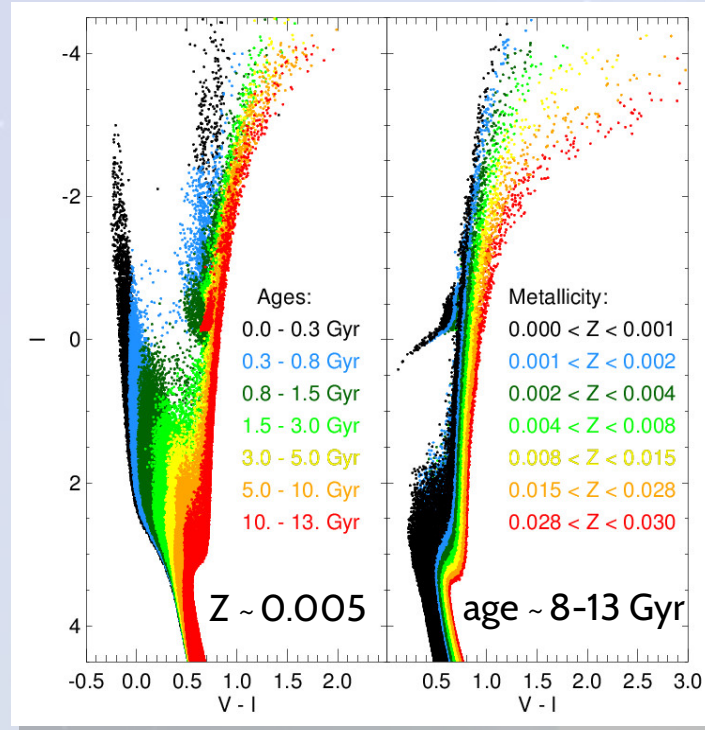

Bernard et al. 2012

# Quantifying the star formation history: color-magnitude diagram fitting

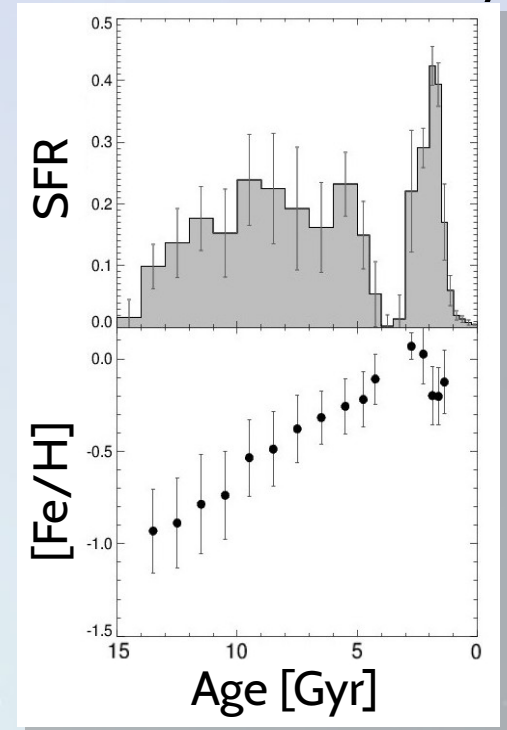

Observations

Stellar evolution models

Star formation history

- Estimate the age and metallicity with a precision of 10-20%

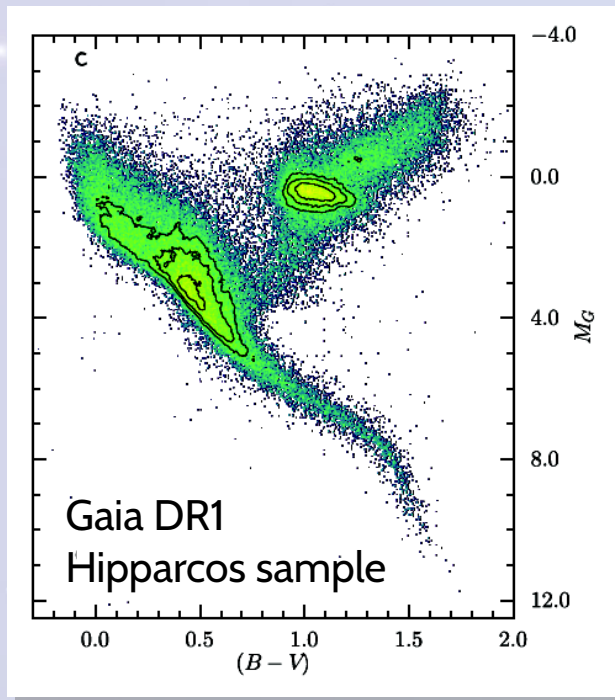

# Gaia DR1 – TGAS

Brown et al. 2016

- Combination of *Hipparcos*, *Tycho-2*, Gaia
- 2 057 050 stars, 90% within 1.5 kpc of the Sun
- Positions
- G-band magnitudes
- proper motions
- stellar parallaxes → intrinsic magnitudes!

# Star Formation Histories from CMD-fitting

Brown et al. 2016

## 3 main requirements:

- depth – to reach the main-sequence turn-off (MSTO)
- well constrained completeness vs. color & magnitude
- accurate colors and magnitude

# Requirement 1: Photometric depth

- Most accurate age estimate from the main-sequence turn-off (MSTO)
- Photometry should be deep and complete enough to sample the MSTO

Brown et al. 2016

Depth limited by *Tycho-2* completeness (Hog et al. 2000):

- $> 90\%$  at  $V < 11.5$
- $(m-M) = 7 \rightarrow 250 \text{ pc}$

# Requirement 1: Photometric depth

- Most accurate age estimate from the main-sequence turn-off (MSTO)
- Photometry should be deep and complete enough to sample the MSTO

Brown et al. 2016

Depth limited by *Tycho-2* completeness (Hog et al. 2000):

- $> 90\%$  at  $V < 11.5$
- $(m-M) = 7 \rightarrow 250$  pc

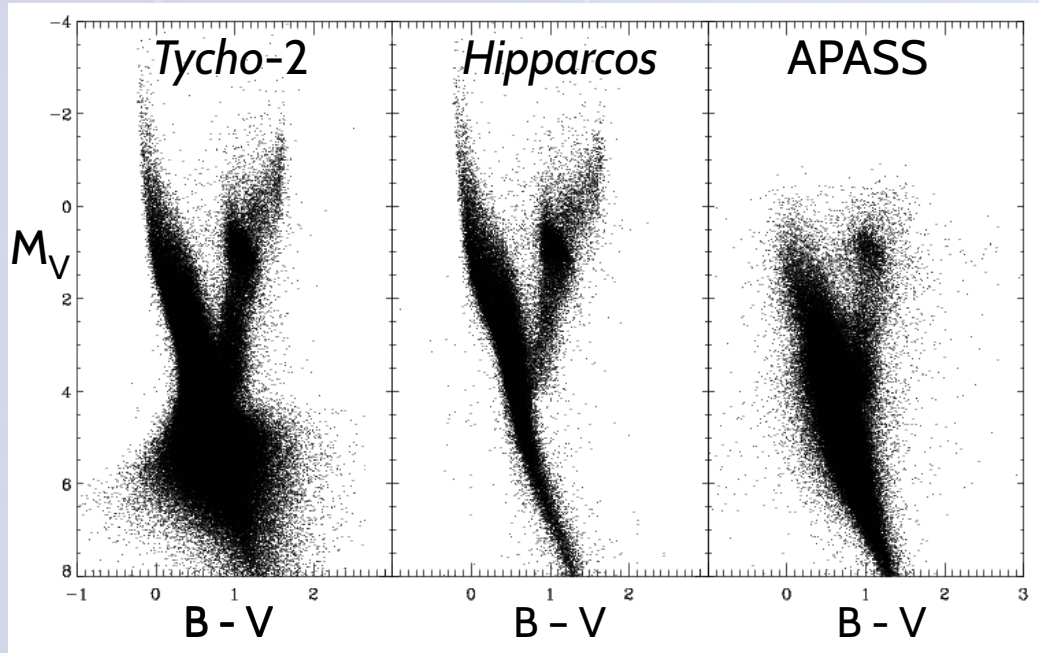

Fractional uncertainty  
on the parallax

## Requirement 2: accurate colors and magnitudes

- Gaia DR1 only provides G-band magnitudes
- No color information → need to cross-match with other catalogs

Out of ~327 000 stars within 250 pc:

- 100 % have *Tycho-2* colors
- 20 % have *Hipparcos* colors
- 77 % have APASS colors

→ weighted average colors

## Requirement 3: known completeness

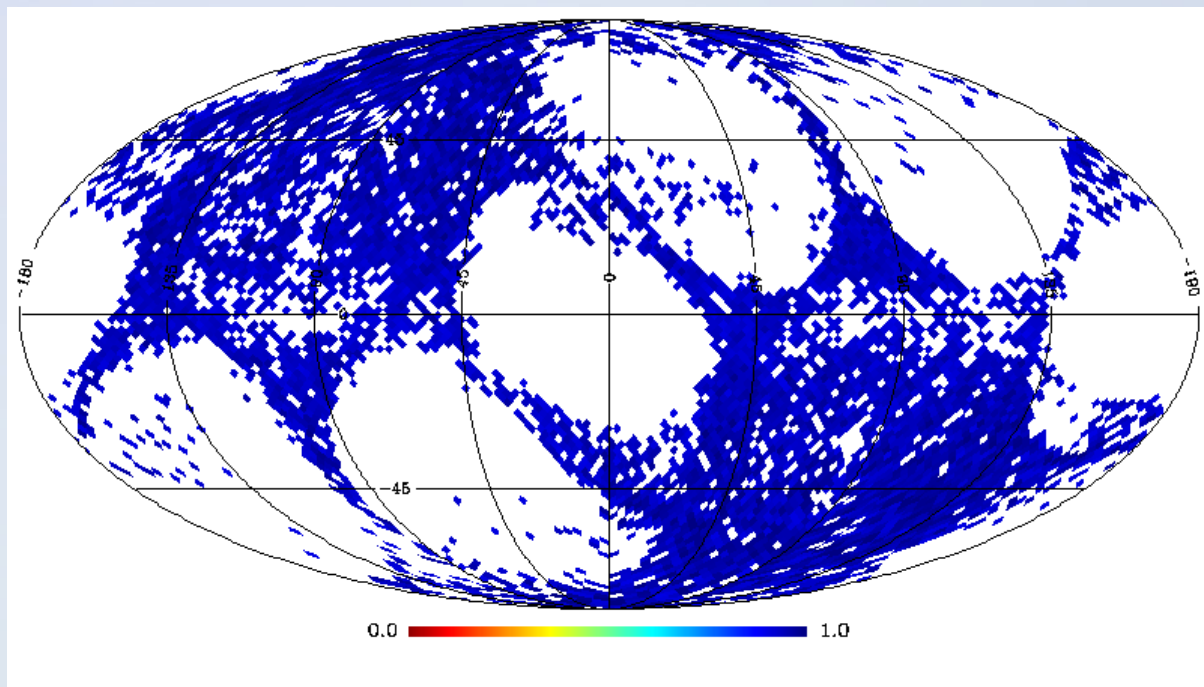

- Within 250 pc, *Tycho-2* is >90% complete down to MSTO
- But only ~80% have TGAS parallaxes!

# Requirement 3: known completeness

## Solution:

- Complete with *Hipparcos* parallaxes
- Excise 57% of the sky area with completeness < 90%

# Resulting color-magnitude diagram

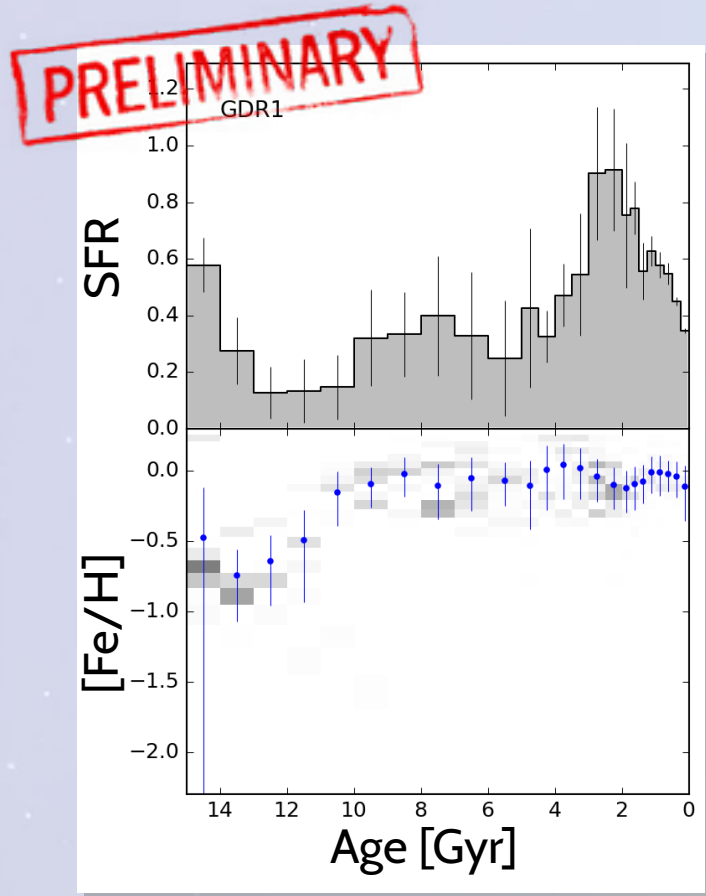

Gaia/Hipparcos/Tycho/APASS  
“volume complete” within 250 pc

Gaia DR1 - Hipparcos sample

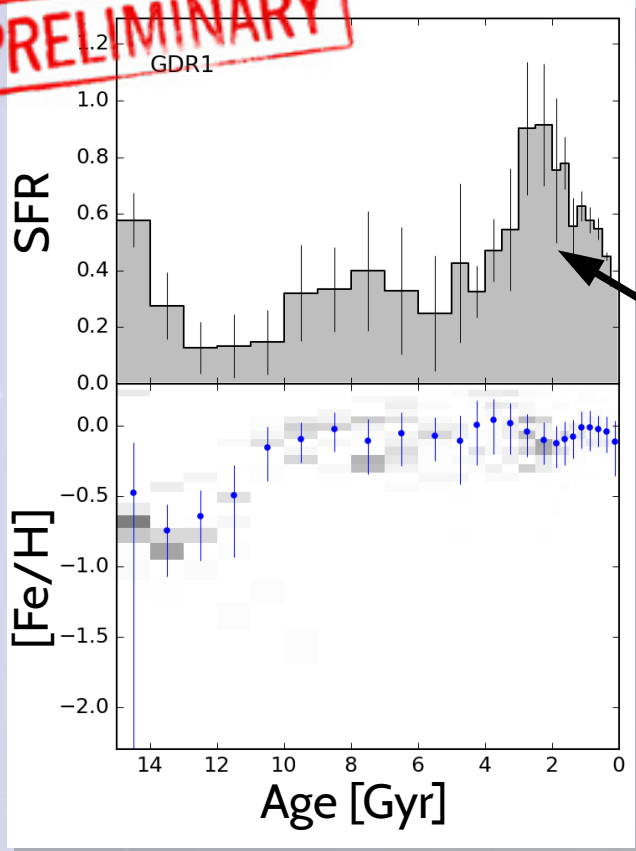

# Star formation history of the disk in the solar neighborhood

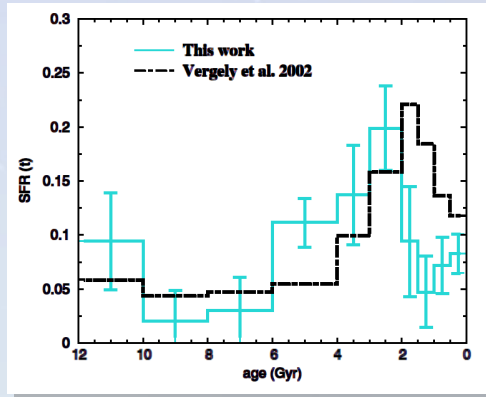

# Star formation history of the disk in the solar neighborhood

**PRELIMINARY**

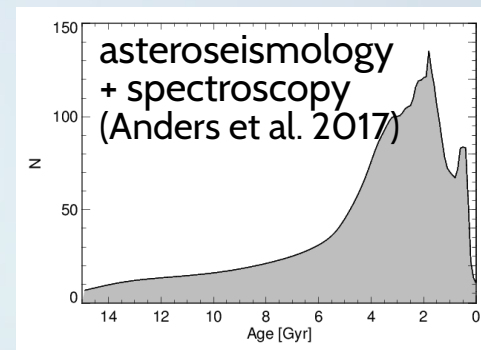

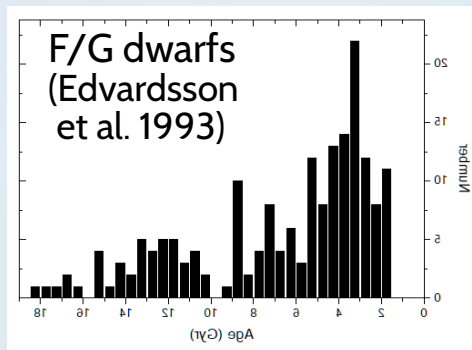

Fully consistent with SFH within 80pc from *Hipparcos* (e.g. Vergely et al. 2002, Cignoni et al. 2006)

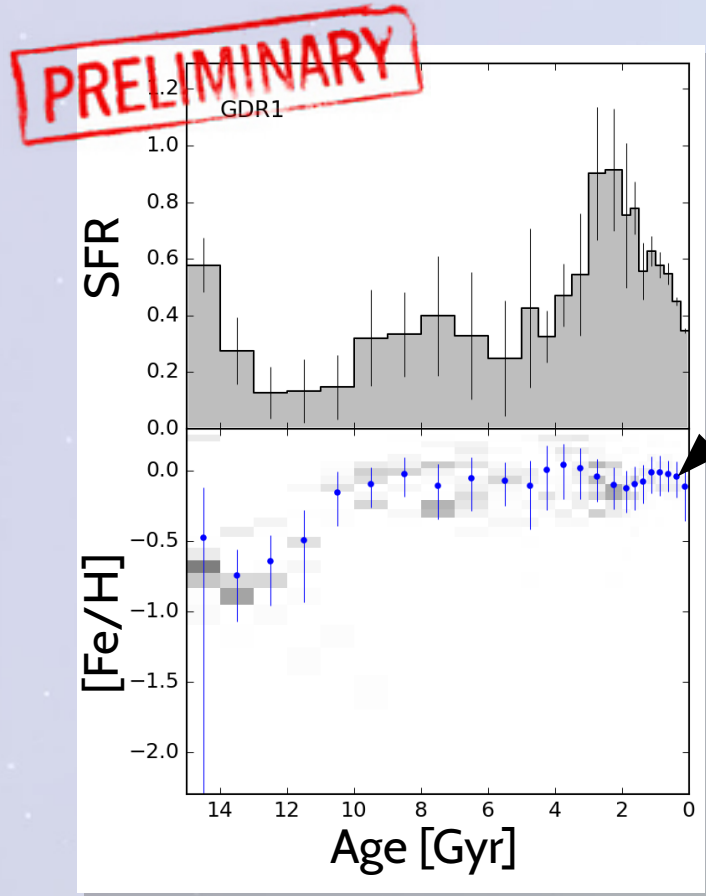

Cignoni et al. 2006

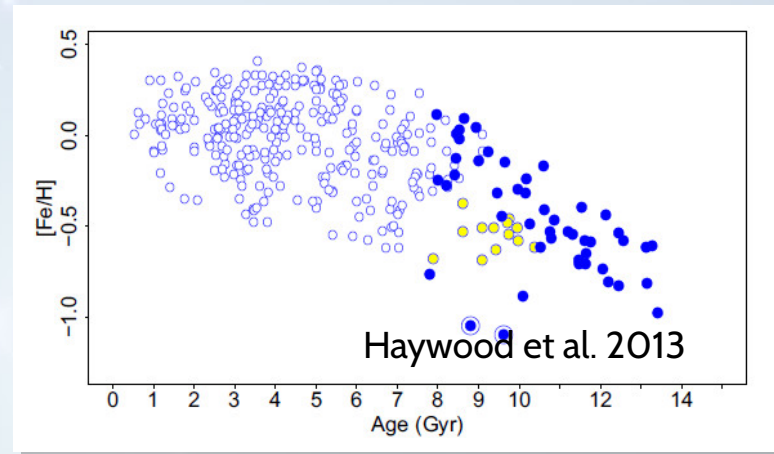

Excess of stars younger than ~4 Gyr

# Star formation history of the disk in the solar neighborhood

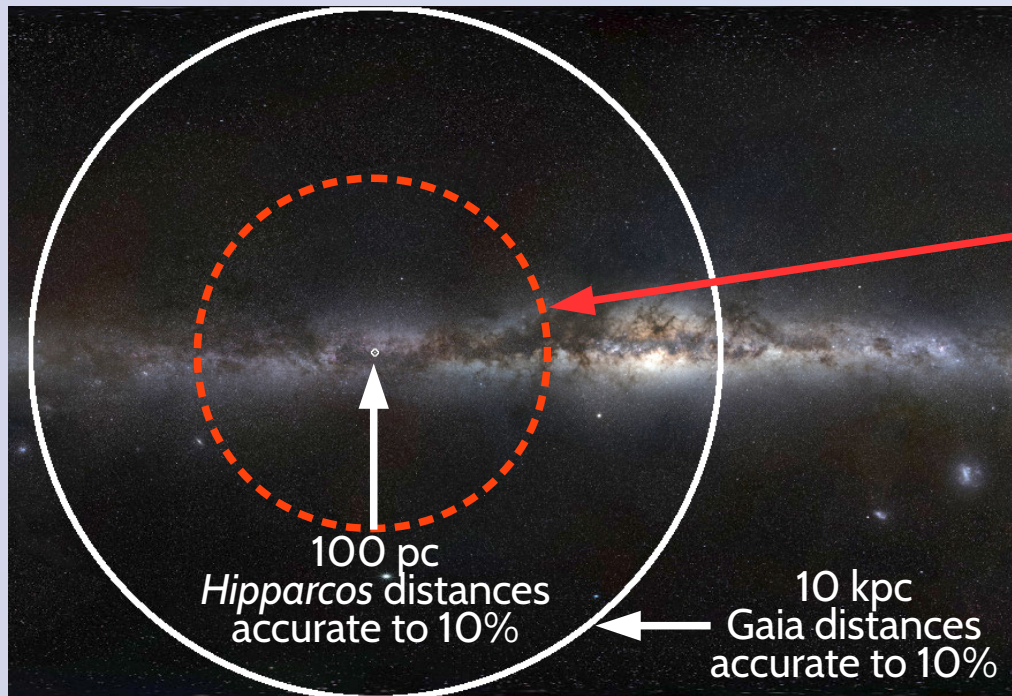

Flat age-metallicity relation in the past ~10 Gyr  
→ consistent with e.g. Geneva-Copenhagen Survey

# Beyond the solar neighborhood: Future Gaia Data Releases

Star formation history of the Milky Way components out to ~4-5 kpc

~5 kpc  
Deep, complete  
Gaia CMDs

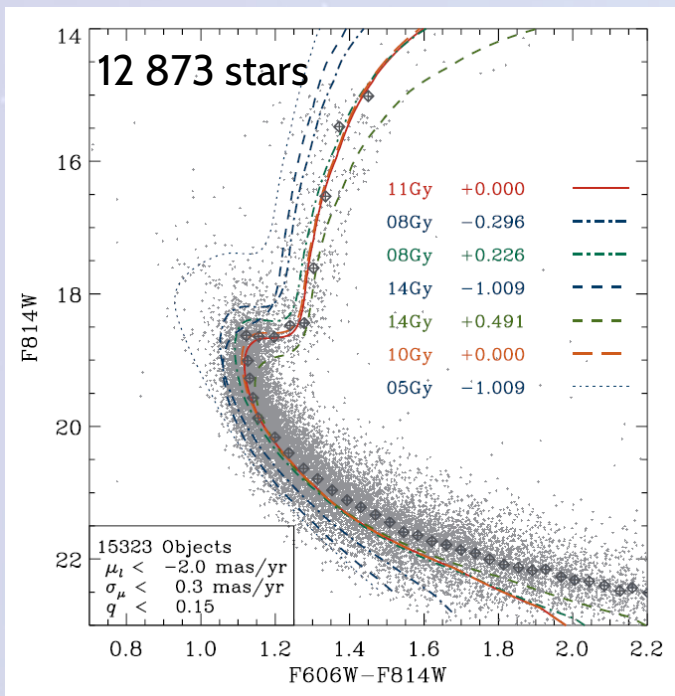

Expected performances from  
In-Orbit Commissioning Review

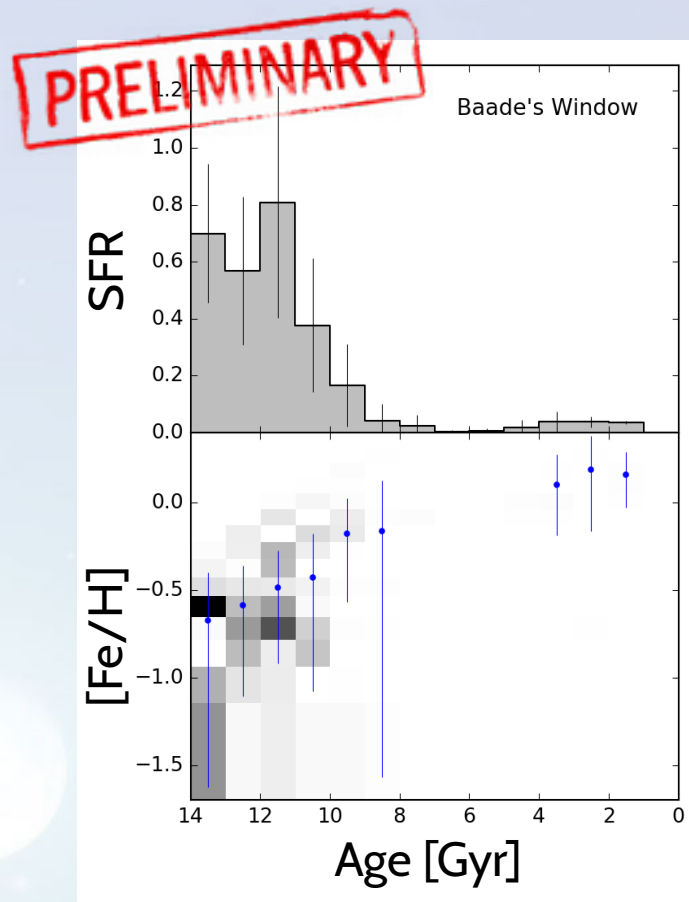

# Star formation history of the Milky Way bulge from *HST* data

Proper-motion cleaned CMD  
of Baade's window

Clarkson et al. 2008

# Summary

- Gaia parallaxes allow the reconstruction of the SFH of the Milky Way
- SFH of the solar neighborhood fully consistent with that from *Hipparcos*
- DR2+ much deeper, more complete, with accurate colors
  - SFH of each Milky Way components
